Pearson's Commitment to Diversity, Equity, and Inclusion

Pearson is dedicated to creating bias-free content that reflects the diversity of all learners. We embrace the many dimensions of diversity, including but not limited to race, ethnicity, gender, socioeconomic status, ability, age, sexual orientation, and religious or political beliefs.

Education is a powerful force for equity and change in our world. It has the potential to deliver opportunities that improve lives and enable economic mobility. As we work with authors to create content for every product and service, we acknowledge our responsibility to demonstrate inclusivity and incorporate diverse scholarship so that everyone can achieve their potential through learning. As the world's leading learning company, we have a duty to help drive change and live up to our purpose to help more people create a better life for themselves and to create a better world.

Our ambition is to purposefully contribute to a world where:

- Everyone has an equitable and lifelong opportunity to succeed through learning.
- Our educational products and services are inclusive and represent the rich diversity of learners.
- Our educational content accurately reflects the histories and experiences of the learners we serve.
- Our educational content prompts deeper discussions with learners and motivates them to expand their own learning (and worldview).

While we work hard to present unbiased content, we want to hear from you about any concerns or needs with this Pearson product so that we can investigate and address them.

- Please contact us with concerns about any potential bias at <https://www.pearson.com/report-bias.html>.

Chapter 1 Deploy Windows client	1
Skill 1.1: Prepare for a Windows client deployment	1
Select a deployment tool based on requirements	2
Choose between migrate and rebuild	10
Choose an imaging and/or provisioning strategy	11
Select a Windows edition based on requirements	17
Plan upgrade and downgrade paths	17
Implement subscription-based activation	21
Windows 11 Enterprise Subscription Activation	23
Skill 1.2: Plan and implement a Windows client deployment by using Windows Autopilot	24
Configure device registration for Autopilot	24
Windows Autopilot deployment scenarios	25
Windows Autopilot requirements	26
Create, validate, and assign deployment profiles	28
Set up the Enrolment Status Page	34
Deploy Windows devices by using Autopilot	37
Troubleshoot an Autopilot deployment	39
Skill 1.3: Plan and implement a Windows client deployment by using MDT	42
Plan and implement an MDT deployment infrastructure	42
Create and manage images	43

Monitor and troubleshoot a deployment	50
Plan and configure user state migration	51
Skill 1.4: Configure remote management	55
Configure Remote Help in Intune	55
Configure Remote Desktop on a Windows client	64
Configure the Windows Admin Center	70
Configure PowerShell remoting and Windows Remote Management (WinRM)	74
Chapter summary	77
Thought experiment	78
Scenario 1	78
Scenario 2	79
Scenario 3	79
Scenario 4	79
Thought experiment answers	80
Scenario 1	80
Scenario 2	80
Scenario 3	81
Scenario 4	81

Chapter 2 Manage identity and compliance 83

Skill 2.1: Manage identity	83
Overview of identity solutions	84
Implement user authentication on Windows devices, including Windows Hello for Business, passwordless, and tokens	86
Manage RBAC for Intune	94
Register devices in and join devices to Azure AD	97
Implement the Intune Connector for Active Directory	107
Manage the membership of local groups on Windows devices	112
Implement and manage LAPS for Azure AD	117
Skill 2.2: Implement compliance policies for all supported device platforms by using Intune	120
Specify compliance policies to meet requirements	121
Manage notifications for compliance policies	124
Implement device compliance policies	125

Monitor device compliance	129
Troubleshoot compliance policies	130
Implement Conditional Access policies that require a compliance status	132
Chapter summary	135
Thought experiment.....	136
Scenario 1	136
Scenario 2	136
Thought experiment answers	137
Scenario 1	137
Scenario 2	137

Chapter 3 Manage, maintain, and protect devices 139

Skill 3.1: Manage the device lifecycle in Intune.....	140
Configure enrollment settings in Microsoft Intune	140
Configure automatic and bulk enrollment	149
Enroll devices	152
Configure policy sets	160
Restart, retire, or wipe devices	162
Skill 3.2: Manage device configuration for all supported device platforms by using Intune.....	163
Specify configuration profiles to meet requirements	164
Implement configuration profiles	168
Monitor and troubleshoot configuration profiles	177
Configure and implement Windows kiosk mode	183
Configure and implement profiles on Android devices	186
Plan and implement Microsoft Tunnel for Intune	187
Skill 3.3: Monitor devices.....	192
Monitor devices by using Intune	192
Monitor devices by using Azure Monitor	198
Analyze and respond to issues identified in Endpoint analytics and Adoption Score	199
Skill 3.4: Manage device updates for all supported device platforms by using Intune.....	201
Plan for device updates	202

Deploy Microsoft 365 Apps by using Intune	258
Configure policies for Office apps by using Group Policy or Intune	263
Deploy apps to platform-specific app stores by using Intune	269
Enable sideloading of apps	285
Skill 4.2: Plan and implement app protection and app configuration policies	288
Plan and Implement App Protection policies for iOS and Android	288
Manage App Protection policies	291
Implement Conditional Access policies for app protection policies	296
To create a Conditional Access policy	296
Plan and implement app configuration policies for managed apps and managed devices	298
Manage App Configuration policies	299
Chapter summary	301

Scenario 2	303
Chapter 5 MD-102 Endpoint Administrator exam updates	305
The purpose of this chapter	305
About possible exam updates	306
Impact on you and your study plan	306
Exam objective updates	306
Updated technical content	306
Objective mapping	306

Acknowledgments

Thank you to the team at Pearson, who helped make the book production process efficient and painless. I'm dedicating this book to Annette and Tommy for being supportive and encouraging. This book is also for the reader. I hope this book helps you proficiently manage Microsoft Windows within a modern cloud environment. The world of IT changes often, and we should all strive to stay up-to-date and use the most appropriate tools. I hope this book helps you to achieve success!

—ANDREW BETTANY

Procrastination is a writer's constant companion, which is nice, because writing can sometimes be a solitary occupation. But working with a great team helps avoid literary dithering and fosters a community spirit. So, I'd like to thank the editorial folks at Pearson for their help and guidance these last few months. I'd also like to thank Nuala, our dog, for giving me plenty of excuses to get up from my desk and go and see what's happening outside. After all, there's always tomorrow.

—ANDREW WARREN

About the authors

ANDREW BETTANY has been awarded the Microsoft Most Valuable Professional (Windows and Devices for IT) for nine years. In 2020, he joined Microsoft for a couple of years to help the Education team drive cloud skills and now helps students globally with achieving skills and certifications via his Cloud Ready Skills programs. He is a loving dad, IT Geek, training mentor, and consultant, entrepreneur, and author.

Andrew is recognized for his Windows expertise and is the author of many publications, including several Windows exam certification prep guides and Microsoft official training materials. He has created video training materials for LinkedIn Learning and Pluralsight. As a Microsoft Certified Trainer for 18 years, Andrew delivers learning and consultancy to businesses in many technical areas, including Microsoft 365, Azure, and Windows.

Andrew is active on social media and can be found on LinkedIn, Facebook, and Twitter. He lives in a village just outside the beautiful city of York in Yorkshire, England.

ANDREW WARREN, MCT, has been writing for Microsoft for many years, helping to develop its official curriculum of instructor-led training material. He has served as a subject matter expert on many Windows Server courses, was technical lead on several Windows client titles, and was involved in Microsoft 365, Azure, and Intune course development. When not writing about Microsoft technologies, he can be found in the classroom, teaching other IT professionals what they need to know to manage their organization's IT infrastructure.

Introduction

With the Microsoft 365 Certified: Modern Desktop Administrator Associate certification, Microsoft has changed how IT Pro certifications work. Rather than being based on a technology area, they are focused on a specific job role. The Microsoft MD-102: Endpoint Administrator exam provides the foundation of this Microsoft 365 Certified: Modern Desktop Administrator Associate certification.

This book covers every major topic area on the exam but does not cover every exam question. Only the Microsoft exam team has access to the exam questions, and Microsoft regularly adds new questions to the exam, making it impossible to cover specific questions. You should consider this book a supplement to your relevant real-world experience and other study materials. If you encounter a topic in this book that you do not feel completely comfortable with, use the “Need more review?” links you’ll find in the text to find more information and take the time to research and study the topic. Great information is available on the Microsoft website at docs.microsoft.com.

Organization of this book

This book is organized by the “Skills measured” list published for the exam. The “Skills measured” list is available for each exam on the Microsoft Learn website: microsoft.com/learn. Each chapter in this book corresponds to a major topic area in the list, and the technical tasks in each topic area determine a chapter’s organization. For example, if an exam covers six major topic areas, the book will contain six chapters.

Preparing for the exam

Microsoft certification exams are a great way to build your resume and let the world know about your level of expertise. Certification exams validate your on-the-job experience and product knowledge. Although there is no substitute for on-the-job experience, preparation through study and hands-on practice can help you prepare for the exam.

We recommend augmenting your exam preparation plan by using a combination of available study materials and courses. For example, you might use the Exam Ref and another study guide for your “at-home” preparation and take a Microsoft Official Curriculum course for the classroom experience. Choose the combination that you think works best for you. Learn more about available classroom training, online courses, and live events at microsoft.com/learn.

Note that this Exam Ref is based on publicly available information about the exam and the author's experience. To safeguard the integrity of the exam, authors do not have access to the live exam.

Microsoft certifications

Microsoft certifications distinguish you by proving your command of a broad set of skills and experience with current Microsoft products and technologies. The exams and corresponding certifications are developed to validate your mastery of critical competencies as you design and develop, or implement and support, solutions with Microsoft products and technologies, both on-premises and in the cloud. Certification brings various benefits to the individual, employers, and organizations.

MORE INFO ALL MICROSOFT CERTIFICATIONS

For information about Microsoft certifications, including a full list of available certifications, go to microsoft.com/learn.

Access the exam updates chapter and online references

The final chapter of this book, "MD-102 Endpoint Administrator exam updates," will be used to provide information about new content per new exam topics, content that has been removed from the exam objectives, and revised mapping of exam objectives to chapter content. The chapter will be made available from the link below as exam updates are released.

This book contains webpage addresses that the author has recommended you visit for more information. Some of these links can be very long and painstaking to type, so we've shortened them for you to make them easier to visit. We've also compiled them into a single list that readers of the print edition can refer to while they read.

The URLs are organized by chapter and heading. Every time you come across a URL in the book, find the hyperlink in the list to go directly to the webpage.

Download the Exam Updates chapter and the URL list at MicrosoftPressStore.com/ERMD102/downloads.

Errata, updates & book support

We've made every effort to ensure the accuracy of this book and its companion content. You can access updates to this book—in the form of a list of submitted errata and their related corrections—at:

MicrosoftPressStore.com/ERMD102/errata

If you discover an error that is not already listed, please submit it to us at the same page.

For additional book support and information, please visit *MicrosoftPressStore.com/Support*.

Please note that product support for Microsoft software and hardware is not offered through the previous addresses. For help with Microsoft software or hardware, go to *support.microsoft.com*.

Stay in touch

Let's keep the conversation going! We're on Twitter: *twitter.com/MicrosoftPress*.

Manage identity and compliance

Two of the most important elements of your IT infrastructure are identity and device compliance. Identity provides knowledge of who somebody or something is, while compliance enables you to determine the overall health of a device. By implementing these two technologies, you can improve your organization's overall security and help protect your organizational data. Compliance policies, especially when implemented with conditional access, are an important part of the MD-102 exam.

Skills covered in this chapter:

- Skill 2.1: Manage identity
- Skill 2.2: Implement compliance policies for all supported device platforms by using Intune

Skill 2.1: Manage identity

Identity services provide authentication and authorization to help protect your organizational resources and data. Over the years, Microsoft has implemented several such identity services: Active Directory Domain Services (AD DS), Azure Active Directory (Azure AD), and Azure AD Domain Services. The MD-102 exam primarily covers content that relates to Azure AD.

This skill covers how to:

- Implement user authentication on Windows devices, including Windows Hello for Business, passwordless, and tokens
- Manage role-based access control (RBAC) for Intune
- Register devices in and join devices to Azure AD
- Implement the Intune Connector for Active Directory
- Manage the membership of local groups on Windows devices
- Implement and manage Local Administrative Passwords Solution (LAPS) for Azure AD

Overview of identity solutions

Before we get into the specific content covered in the exam, it's perhaps worth reviewing these identity providers. There are two identity providers you must be familiar with in the Endpoint Administrator role:

- **AD DS** Windows Server role used to support identity in on-premises environments
- **Azure AD** Cloud-based identity solution used to provide single sign-on (SSO) for cloud apps such as Microsoft 365 and Azure

A third identity provider, Azure AD Domain Services, is a managed Azure service that provides an identity solution that closely resembles the behavior of AD DS but runs in the cloud without needing Windows server computers configured as domain controllers. This identity solution is out of this course's scope.

NEED MORE REVIEW? IMPLEMENT HYBRID IDENTITY WITH WINDOWS SERVER

For more information about Azure AD Domain Services, refer to the Microsoft Learn website at <https://learn.microsoft.com/training/modules/implement-hybrid-identity-windows-server>.

Active Directory Domain Services

Detailed knowledge of Windows Server and AD DS is outside the scope of the MD-102 exam. However, it's probably worth at least discussing the fundamentals of AD DS to help put Azure AD into context.

AD DS, commonly referred to as either Windows Active Directory or just Active Directory, is a role of associated services installed on Windows Servers. Windows Server installed with the AD DS role is a complex environment that has benefitted organizations for more than 20 years and has many legacy components necessary to support AD feature backward compatibility. AD DS has the following features:

- Hierarchical and granular and based on the X.500 standard.
- Implements Lightweight Directory Access Protocol (LDAP) for managing directory objects.
- Administrative ability is defined by group membership.
- Objects are stored in containers called organizational units (OUs) that represent the structure of your organization, as shown in Figure 2-1.
- Group Policy manages the administration of objects, as indicated in Figure 2-1.
- Kerberos protocol is primarily used for AD DS authentication.
- Computer objects represent computers that join an Active Directory domain.

NOTE JOINING AN AD DS DOMAIN

Only computers running the Windows operating system can be domain-joined.

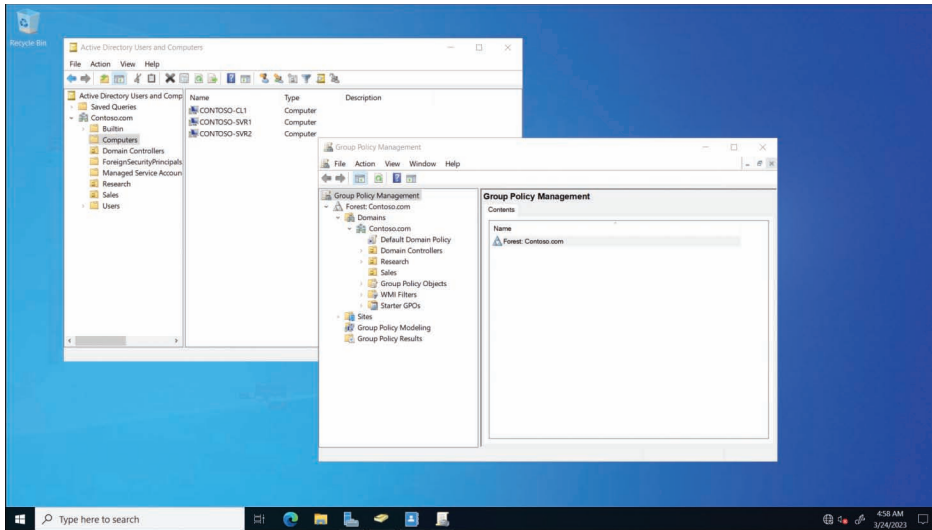

FIGURE 2-1 Management tools on an Active Directory domain controller

Azure Active Directory

Microsoft provides each cloud-based services subscriber, such as Microsoft 365, an instance of Azure AD (a tenant). Organizations can choose to add additional subscriptions, such as Microsoft Azure, and use the same Azure AD tenant for authentication and authorization. Alternatively, organizations can implement a separate Azure AD tenant for each subscribed service or app.

When you subscribe to a cloud service, like Microsoft 365, you can select a specific edition of Azure AD. The free version of Azure AD provides capabilities useful to most organizations; however, paid Azure AD Premium editions are also available, adding capabilities more relevant to large organizations.

It's important not to think of Azure AD as Active Directory in the cloud; instead, it's an entirely different authentication and authorization solution designed to support the cloud environment, unlike AD DS. Azure AD has the following features:

- Is flat, with no container hierarchy
- Provides for less fine-grained administrative control
- Uses role-based access control (RBAC)
- Supports administration management with profiles and group assignments
- Relies on Security Assertion Markup Language (SAML) and Open Authorization (OAuth)

When working with devices, you can add devices to Azure AD that are running a variety of operating systems, including

- Android
- iOS

- Linux
- macOS
- Windows 10 and newer

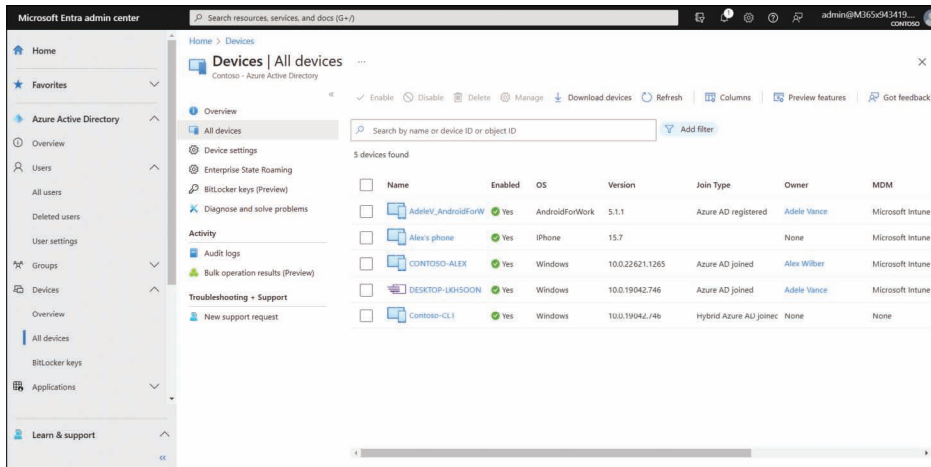

FIGURE 2-2 The Microsoft Entra admin center displaying the Azure Active Directory | All devices folder.

Implement user authentication on Windows devices, including Windows Hello for Business, passwordless, and tokens

You can sign in to your Windows 11 computer by using a variety of user accounts, depending on the configuration of your computer. The following list describes these account types:

- **Microsoft account** A consumer Microsoft account, often with an Outlook.com or Hotmail.com suffix.
- **Microsoft 365 account** An Azure AD account, usually called a Work or School account. Typically has an organizational suffix, such as Contoso.com. When a user adds a Work or School account to their device, they sign in using those account details; all services and apps accessed by the user automatically use the account to authenticate; this provides for cloud-based SSO.

EXAM TIP

By default, all Azure AD accounts are configured with a default tenant domain suffix. This default suffix is created when you obtain your Microsoft 365 subscription and always ends with `.onmicrosoft.com`. When configuring your Azure AD tenant, you typically add a custom domain name, such as `Contoso.com`, that your organization owns. Users can then sign in using either the custom domain suffix or the default domain suffix, although users find it easier and more logical to use the custom domain suffix.

- **Domain account** An AD DS account. If a computer is AD DS domain-joined, then a user can sign in at their computer using a domain account. When a user signs in using a domain account, all services and apps accessed by the user automatically use the account to authenticate; this provides for AD DS forest-wide SSO.
- **Local account** A computer user account. Typically, Windows 11 computers have local user and group accounts. A user might sign in using a local account when the computer belongs to them rather than the organization they work for. When users sign in using local accounts, they must configure the organizational account for each app or service they want to connect to. For example, they must add a Work or School account as part of a Microsoft Outlook profile to connect to Exchange Online.

Most users are probably familiar with signing in using a username and password. While that's acceptable and fairly common, Microsoft has added support for different authentication methods in Windows 11. These methods are designed to improve the sign-in experience and help make it more secure.

Understand multifactor authentication

Traditional computer authentication is based on users providing a name and password. This enables an authentication authority to validate the exchange and grant access. Although password-based authentication is acceptable in many circumstances, Windows 11 provides a number of additional more secure methods for users to authenticate with their devices, including multifactor authentication (sometimes referred to as two-factor authentication).

Multifactor authentication is based on the principle that users who want to authenticate must have two (or more) things to identify themselves:

- Know something (such as a password)
- Have something (such as a security token)
- Be something (such as fingerprints or biometrics)

For example, a user might know a password, have a security token (in the form of a digital certificate), and be able to prove who they are with biometrics, such as fingerprints or facial recognition.

EXPLORE BIOMETRICS

Biometrics, such as a fingerprint, provides more secure and often more convenient methods for identifying and verifying users and administrators. Windows 11 includes native support for biometrics through the Windows Biometric Framework (WBF), and when used as part of a multifactor authentication plan, biometrics is increasingly replacing passwords in modern workplaces.

Biometric information is obtained from the individual and stored as a biometric sample which is then securely saved in a template and mapped to a specific user. You can use a fingerprint reader to capture a person's fingerprint. (You "enroll" the user when configuring this.) Also, you can use a person's face, retina, or even voice. The Windows Biometric service can also be extended to include behavioral traits, such as body gait and typing rhythm.

Windows includes several Group Policy settings related to biometrics, as shown in Figure 2-3, that you can use to allow or block biometrics from your devices. You can find Group Policy Objects here: Computer Configuration\Administrative Templates\Windows Components\Biometrics.

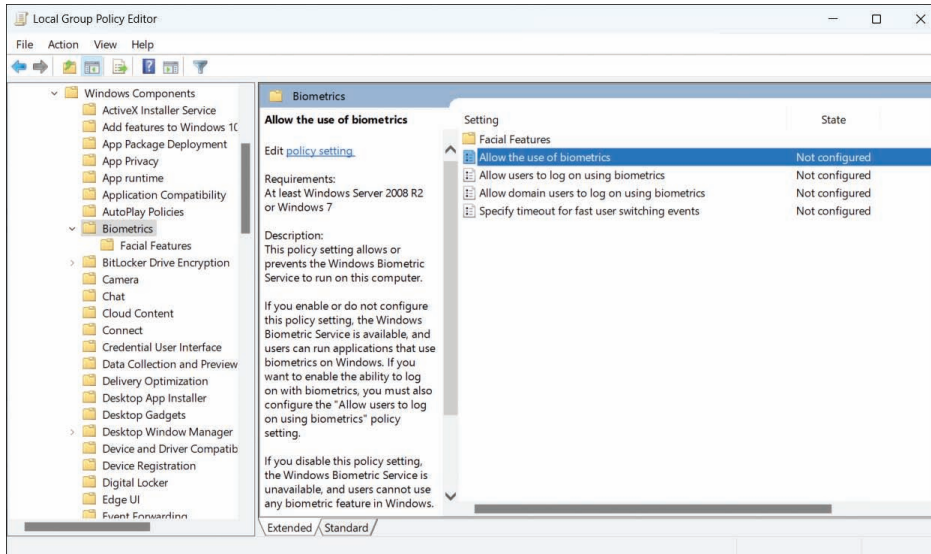

FIGURE 2-3 Biometrics Group Policy settings

Configure Windows Hello and Windows Hello for Business

Windows Hello is a two-factor biometric authentication mechanism built into Windows 11, and it is unique to the device on which it is set up. Windows Hello enables users to unlock their devices using facial recognition, fingerprint scanning, or a PIN.

Windows Hello for Business is the enterprise implementation of Windows Hello and enables users to authenticate to an AD DS or Azure AD account, and it allows them to access network resources. Administrators can configure Windows Hello for Business using Group Policy or mobile device management (MDM) policy and use asymmetric (public/private key) or certificate-based authentication.

Windows Hello provides the following benefits:

- Strong passwords can be difficult to remember, and users often reuse them on multiple sites, reducing security. Windows Hello enables them to authenticate using their biometric data.
- Passwords are vulnerable to replay attacks, and server breaches can expose password-based credentials.
- Passwords offer less security because users can inadvertently expose their passwords because of phishing attacks.

- Windows Hello helps protect against credential theft. Because a malicious person must have both the device and the biometric information or PIN, it becomes more difficult to hack the authentication process.
- Windows Hello can be used both in cloud-only and hybrid deployment scenarios.
- Windows Hello signs you into your devices much faster than when using a password.

To implement Windows Hello, your devices must have the appropriate hardware. For example, facial recognition requires using special cameras that see infrared (IR) light. These can be external cameras or cameras incorporated into the device. The cameras can reliably distinguish between a photograph and a living person. For fingerprint recognition, your devices must be equipped with fingerprint readers, which can be external or integrated into laptops or USB keyboards.

NOTE LEGACY FINGERPRINT READERS

If you have previously experienced poor reliability from legacy fingerprint readers, you should review the current generation of sensors, which offer significantly better reliability and are less error-prone.

After you have installed the necessary hardware devices, you can set up Windows Hello by opening **Settings**, selecting **Accounts**, and then, on the **Sign-In Options** page, under the **Ways to sign in** heading, reviewing the options for facial or fingerprint recognition. You can still configure a PIN or use a Security key if you do not have Windows Hello–supported hardware.

To configure Windows Hello for facial recognition, follow these steps:

1. Open **Settings** and select **Accounts**.
2. On the **Accounts** page, select **Sign-In Options**.
3. Under the **Ways to sign in** heading, select **Facial recognition (Windows Hello)**.
4. Click **Set up**, and when prompted, click **Get started**.
5. Enter your PIN or password to verify your identity.
6. Allow Windows Hello to capture your facial features, as shown in Figure 2-4.
7. After completion, you are presented with an **All Set!** Message, indicating that you can close the dialog.

Users can use Windows Hello for a convenient and secure sign-in method tied to the device on which it is set up.

For Enterprises that want to enable Windows Hello, they can configure and manage Windows Hello for Business. Windows Hello for Business uses key-based or certificate-based authentication for users by using Group Policy or mobile device management (MDM) policy or a mixture of both methods.

FIGURE 2-4 Configuring Windows Hello

NEED MORE REVIEW? WINDOWS HELLO BIOMETRICS IN THE ENTERPRISE

To review further details about using Windows Hello in the enterprise, refer to the Microsoft website at <https://docs.microsoft.com/windows/access-protection/hello-for-business/hello-biometrics-in-enterprise>.

CONFIGURE PIN

To avoid authentication with passwords, Microsoft provides an authentication method that uses a PIN. When you set up Windows Hello, you're asked to create a PIN first. This PIN enables you to sign in using the PIN as an alternative when you can't use your preferred biometric because of an injury or because the sensor is unavailable or not working properly. The PIN provides the same level of protection as Windows Hello.

Windows Hello PIN provides secure authentication without sending a password to an authenticating authority, such as Azure AD or an AD DS domain controller. Windows Hello for Business provides enterprises with compliance with the new FIDO 2.0 (Fast ID Online) framework for end-to-end multifactor authentication.

A user cannot use a PIN alone (known as a convenience PIN) within a domain environment. Figure 2-5 shows that the PIN settings are known as the Windows Hello PIN. A user must first configure Windows Hello and already be signed in using a local account, a domain account, a Microsoft account, or an Azure AD account. The user can then set up PIN authentication associated with the credential for the account.

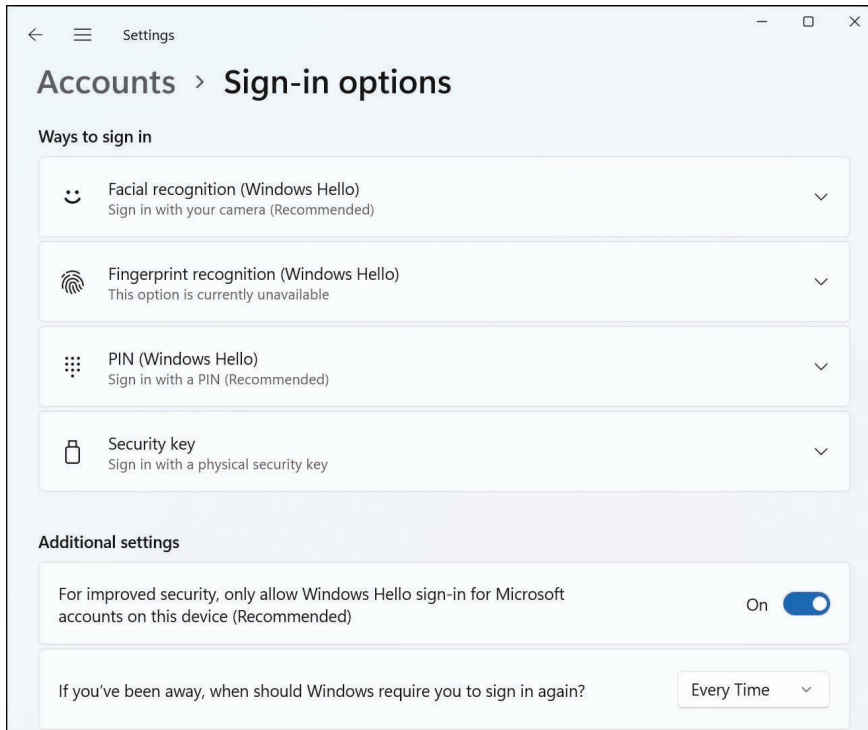

FIGURE 2-5 Configuring Windows Hello PIN

After a user has completed the registration process, Windows Hello for Business generates a new public-private key pair on the device known as a *protector key*. If installed in the device, the Trusted Platform Module (TPM) generates and stores this protector key; if the device does not have a TPM, Windows encrypts the protector key and stores it on the file system. Windows Hello for Business also generates an administrative key to reset credentials if necessary.

NOTE PAIRING OF CREDENTIALS AND DEVICES

Windows Hello for Business pairs a specific device and a user credential. Consequently, the PIN chosen by the user is associated only with the signed-in account and that specific device.

The user now has a PIN *gesture* defined on the device and an associated protector key for that PIN gesture. The user can now securely sign in to his device using the PIN and then add support for a biometric gesture as an alternative to the PIN. The *gesture* can be facial recognition, iris scanning, or fingerprint recognition, depending on the available device hardware. When a user adds a biometric gesture, it follows the same basic sequence mentioned in the previous section. The user authenticates to the system using the PIN and then registers the new biometric. Windows generates a unique key pair and stores it securely. The user can then sign in using the PIN or a biometric gesture.

NEED MORE REVIEW? WINDOWS HELLO FOR BUSINESS

To review further details about deploying Windows Hello for Business within an enterprise environment, refer to the Microsoft Learn website at <https://learn.microsoft.com/windows/security/identity-protection/hello-for-business/hello-identity-verification>.

You can use MDM policies or GPOs to configure your organization's Windows Hello for Business settings. For example, you can configure a policy that enables or disables the use of biometrics on devices affected by the policy.

NOTE ENHANCING THE SECURITY OF A PIN

When we think of a PIN, we generally think of ATM cash machines and 4-digit PINs. For securing Windows 11 with Windows Hello for Business, you can significantly increase the level of security by imposing rules on PINs so that, for example, a PIN can require or block special characters, uppercase characters, lowercase characters, and digits. Something like t496A? could be a complex Windows Hello PIN. The maximum length that can be set is 127.

USING GROUP POLICY TO CONFIGURE WINDOWS HELLO FOR BUSINESS

To configure Windows Hello for Business in your on-premises organization, you use the appropriate GPOs within the following location:

Computer Configuration\Policies\Administrative Templates\Windows Components\
Windows Hello for Business

To configure PIN complexity with Windows 11 (with and without Windows Hello for Business), you can use the eight PIN Complexity Group Policy settings, which allow you to control PIN creation and management.

You can deploy these policy settings to computers or users. If you deploy settings to both, then the user policy settings have precedence over computer policy settings, and GPO conflict resolution is based on the last applied policy. The policy settings included are:

- Require digits
- Require lowercase letters
- Maximum PIN length
- Minimum PIN length
- Expiration
- History
- Require special characters
- Require uppercase letters

In Windows 11, the PIN complexity Group Policy settings are located at: Administrative Templates\System\PIN Complexity (under both the **Computer** and **User Configuration** nodes).

NEED MORE REVIEW? WINDOWS HELLO FOR BUSINESS POLICY SETTINGS

To review more detailed configuration steps for Windows Hello for Business within an enterprise environment, refer to the Microsoft Learn website at <https://learn.microsoft.com/windows/security/identity-protection/hello-for-business/hello-cert-trust-policy-settings>.

If your organization is not using Windows Hello for Business, you can still use the option to set a Convenience PIN. A Convenience PIN is very different from a Windows Hello for Business PIN because it is merely a wrapper for the user's domain password. This means that the user's password is cached and substituted by Windows when signing in with a Convenience PIN.

The option to allow a Convenience PIN is disabled by default for domain-joined clients. To enable this feature, enable the **Turn On Convenience PIN Sign-In GPO** value located at Computer Configuration\Administrative Templates\System\Logon.

USING INTUNE TO CONFIGURE WINDOWS HELLO FOR BUSINESS

To configure the required Windows Hello for Business settings using Intune, open the Microsoft Intune admin center and then create a device configuration profile with the **Identity protection** type. Use the following procedure:

1. In the Microsoft Intune admin center, select **Devices > Windows** and click **Configuration Profiles**.
2. Click **Create profile**, select **Windows 10 and later**, and then select **Identity protection** from the list of templates.
3. Click **Create**, and then on the **Basics** tab, provide a name and description. Click **Next**.
4. On the **Configuration settings** tab, enable the **Configure Windows Hello for Business** setting.
5. As shown in Figure 2-6, you can configure the required settings described earlier. Click **Next**.
6. On the **Assignments** tab, assign the policy to the desired group, click **Next**, and then complete the wizard to complete the profile configuration.

You can also achieve the same result by using an Account protection policy in Endpoint security. Account protection policies support the configuration of the following:

- Local user group membership
- Local admin password solution (LAPS)
- Account protection

Choose **Account protection**. You can then follow a similar wizard-driven procedure to configure Windows Hello for Business settings.

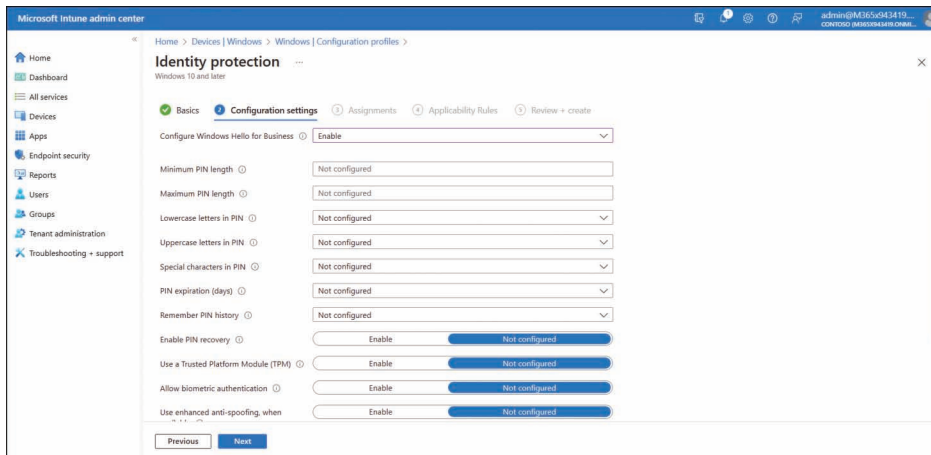

FIGURE 2-6 Enabling Windows Hello for Business with Intune

Manage RBAC for Intune

In Windows Server and Windows 11, users are assigned administrative ability through group membership. Typically, built-in groups are used to support this process. For example, to enable a user to perform server management tasks, you can add their user account to the Server Operators local group. Because the Server Operators local group has been automatically assigned numerous management abilities, a user added to that group inherits the abilities of that group. This process is referred to as group-based security.

In Intune, a different process is used; this process is called role-based access control. Although you can use RBAC to assign management and administrative permissions in Intune, RBAC is usually managed in Azure AD. Although your job function might not entail configuring RBAC in Azure AD, it's probably worth reviewing some of the available settings.

Configuring RBAC in Azure AD

There are numerous built-in roles in Azure AD. You can rely solely on these roles and, for many situations, they'll provide you with the necessary management delegation you likely need. However, you can also create custom roles; these are roles for which you define the management permissions to suit your specific organizational requirements.

You use the Microsoft Entra admin center or the Azure Active Directory admin center to manage and assign roles.

NOTE MICROSOFT ENTRA OR AZURE ACTIVE DIRECTORY ADMIN CENTER

You can use either of these management consoles to perform Azure AD management and administration tasks. However, because Microsoft Entra is the newer administrative console, we focus on that throughout this book.

In Microsoft Entra, expand **Azure Active Directory** in the navigation pane, then expand **Roles & admins**. Select the **Roles & admins** node, as displayed in Figure 2-7.

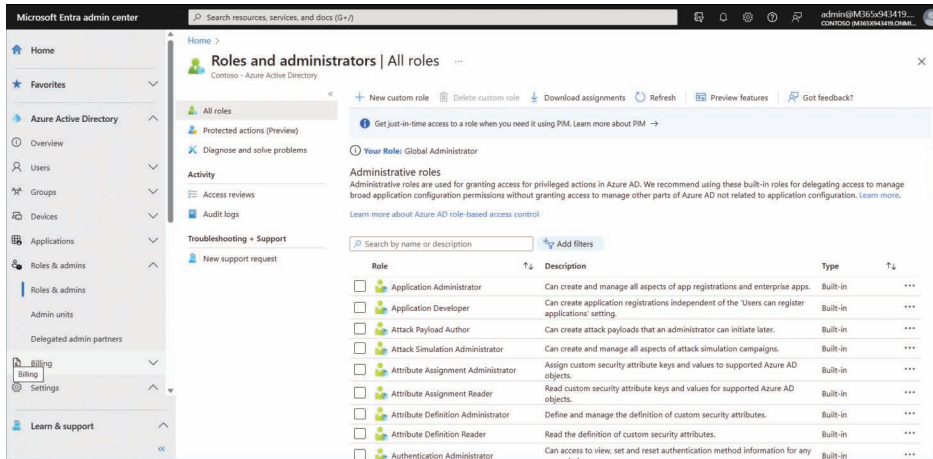

FIGURE 2-7 Reviewing RBAC roles in Microsoft Entra

You can search for a specific role and then review who has that role assigned. For example, in the search box, enter **Intune** and then select the **Intune Administrator** role from the returned list.

On the **Assignments** tab, you can review and modify role-holders. To add an assignment, use the following procedure:

1. Click **Add assignments**.
2. Click the **No member selected** link.
3. In the **Select a member** pane, select a user or group to which you want to assign the role. Click **Next**.
4. You can now choose between the following options:
 - **Eligible** Means that the user can exercise the permissions of the assigned role. You can then make the assignment permanently eligible or define a time range. When a user is eligible for a role, a designated administrator must confirm their use of that role when the user attempts to exercise their administrative permissions.
 - **Active** Means the user can immediately exercise the administrative permissions associated with the assigned role.

NOTE PRIVILEGED IDENTITY MANAGEMENT

The choice between Eligible and Active is only possible when “Privileged Identity Management (PIM)” is activated in the Azure subscription.

5. Click **Assign**.

NOTE ASSIGN ROLES TO GROUPS

It's best practice to assign a role to a group—even if it contains only one user. This is because it makes ongoing administration easier. For example, if the Azure AD security group **Contoso Device Admins** contains a user called AndrewW, and you have assigned the Intune Administrator role to Contoso Device Admins, AndrewW has that through their group membership. To remove that role from AndrewW, you merely need to remove AndrewW from the Contoso Device Admins group. You might then add Sa11yM to the Contoso Device Admins group, thereby assigning the Intune Administrator role to Sa11yM. It's important that when you create groups you intend to use in this way, you remember to enable the **Azure AD roles can be assigned to the group** option.

When you assign a role, you can assign it to the entire directory (which means everything in your Azure AD tenant), or you can use Admin units. These are similar to organizational units (OUs) in an on-premises AD DS infrastructure, allowing for a more targeted delegation of admin permissions.

You define the scope of the role when you add a user or group to the role. That's to say, you select the **Scope type** option on the **Add assignments** page, as displayed in Figure 2-8. You can then select either **Directory** (the default) or **Administrative unit**. You must then choose the appropriate admin unit.

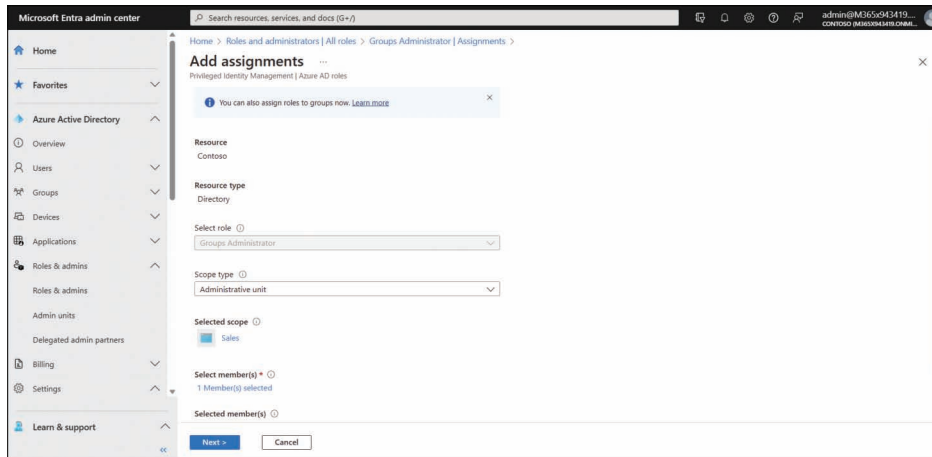

FIGURE 2-8 Scoping the application of a role

As an Endpoint Administrator, your job role entails performing device management and related tasks. In Azure AD, there are a number of relevant RBAC roles for administrative tasks in Microsoft Intune. These are:

- **Intune Administrator** Role holders can manage all aspects of Microsoft Intune.
- **Azure AD Joined Local Administrator** Users assigned to this role are added to the local administrators group on Azure AD-joined devices.

- **Cloud Device Administrator** Users with this role have limited device management capabilities, including enabling, disabling, and deleting devices.

Configuring RBAC in Intune

Although you'll typically manage roles and role assignments in Microsoft Entra, you can also manage these roles directly in Intune. Or, more accurately, you can manage role assignments in Intune. To review or change role assignments using the Microsoft Intune admin center, use the following procedure:

1. Select the appropriate user account.
2. On the user details page, select **Assigned roles** in the navigation pane.
3. Review or update the assigned roles as shown in Figure 2-9.

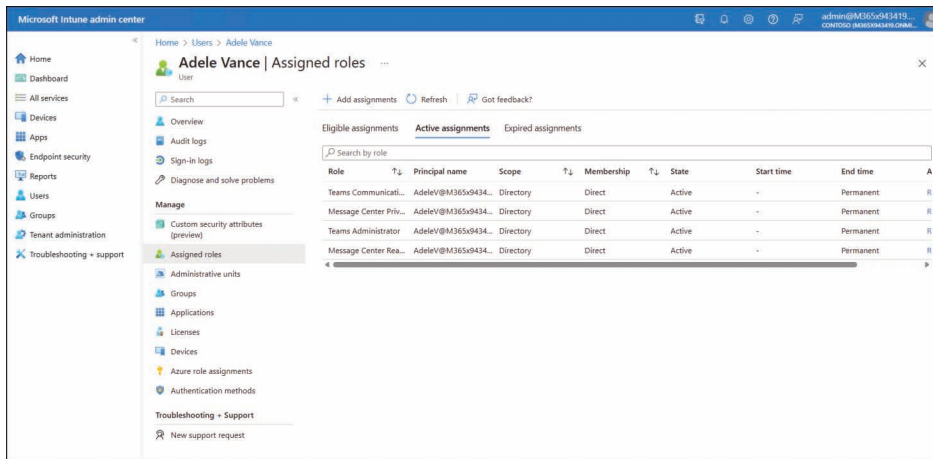

FIGURE 2-9 Updating role assignments in Intune

Register devices in and join devices to Azure AD

Microsoft designed Windows 11 to be remotely managed using cloud-based tools, such as Microsoft Intune. As more organizations migrate to the cloud, you must understand how to configure your users' devices to register them in Azure AD.

In this section, you'll learn how to register a device so a workplace or school with cloud-based services can manage it. You'll learn how to enable device registration and join devices to Azure AD.

Understand device management

When joining devices to an on-premises domain environment, the types of devices you can join to the domain are quite restrictive; devices, for example, must be running a supported operating system. This means that any users that have devices running Windows 11 Home editions cannot join the company's on-premises domain.

However, Azure AD is less restrictive in this respect; you can add to Azure AD almost any tablet, laptop, smartphone, and desktop computer running various operating systems. When you enable users to add their devices to Azure AD, you will manage their enrolled devices using an MDM solution, such as Microsoft Intune, which enables you to manage and provision your users' devices.

You can connect your devices to Azure AD in one of two ways. These are:

- Registering a device to Azure AD
- Joining a device to Azure AD

To understand these options, it's worth considering an on-premises scenario. Suppose you want to connect a computer to a workplace file server. Let's assume your computer is configured in a workgroup—a standalone configuration. You'll perform the following procedure:

1. Sign in to your computer using a local user account.
2. Connect your computer to the corporate network infrastructure.
3. Open File Explorer and map a network drive to a target file server shared folder.
4. Provide credentials to authenticate with the server. These credentials are in AD DS and stored in a domain controller.
5. Access your mailbox in your organization's Exchange Server by creating an Outlook profile that enables connectivity to the Exchange environment, including the credentials required to access the mailbox.

The process is decentralized and requires manual configuration to access resources in your corporate environment. Contrast that to a domain-joined workstation:

1. You sign in to the domain-joined workstation using a domain account.
2. You map a network drive to a file server. The server uses your existing credentials to authenticate you.
3. You open Outlook. Your Exchange Server mailbox server uses your existing credentials to authenticate you.

Using domain-joined devices has enabled SSO, ensuring all apps can be accessed using the signed-in credentials. This is very convenient for the user.

In some ways, you can consider an Azure AD-registered Windows 11 computer to be functionally equivalent to an on-premises, workgroup-configured computer. The user signs in using a local account and then uses a work or school account to access cloud apps and services, having to provide the credentials each time they connect to a new app or service.

Similarly, an Azure AD-joined device behaves much like a computer joined to an AD DS domain. The user signs in with their work or school account, and then all apps and services use these credentials thereafter, providing a better user experience.

Let's examine these two options more closely.

AZURE AD–REGISTERED DEVICES

Windows devices can be registered with Azure AD or joined to Azure AD. Other operating systems, such as iOS, Linux, macOS, and Android, can only be registered.

Generally, corporately owned devices running Windows should be Azure AD-joined, whereas users' own devices running Windows should be registered with Azure AD.

EXAM TIP

Remember, ONLY Windows devices can be joined to Azure AD.

After a user registers or joins their device with Azure AD, it is “known” to Azure AD, and information about the device is stored in Azure AD. Effectively, the device is given an identity with Azure AD. You can then create conditional access policies to determine whether access to resources from your users' devices will be granted.

Azure AD–registered devices enable users to use personally owned devices to access your organization's resources in a controlled manner. Azure AD supports Bring Your Own Device (BYOD) scenarios for multiple devices, including Windows 11, iOS, Android, and macOS.

With an Azure AD–registered device, the user gains access to resources using a work or school Azure AD account at the time they access the resources. All corporate data and apps are kept completely separate from the personal data and apps on the device. If the personal computer, tablet, or phone that is registered with Azure AD doesn't meet your corporate standards for security and compliance—for example, if a device is not running a supported version of the operating system or has been rooted—the access to the resource is denied.

The main reasons for implementing device registration are

- Enabling access to corporate resources from nondomain-joined or personally owned devices.
- Enabling SSO for specific apps and/or resources managed by Azure AD.

After you enable device registration, users can register and enroll their devices in your organizational tenant. After they have enrolled their devices

- Enrolled devices are associated with a specific user account in Azure AD.
- A device object is created in Azure AD to represent the physical device and its associated user account.
- A user certificate is installed on the user's device.

AZURE AD–JOINED DEVICE

Joining a Windows 11 device to Azure AD is similar to registering a device with Azure AD, but it enables enhanced management capabilities. After a device has been joined to Azure AD, the local state of a device changes to enable your users to sign into the device using the work or school account instead of a local account.

An enterprise typically joins its owned devices to the Azure AD to allow for cloud-based management of the devices and to grant access to corporate apps and resources.

Organizations of any size can deploy Azure AD Join. Azure AD Join works well in a cloud-only (no on-premises infrastructure) environment. When Azure AD Join is implemented in a hybrid environment, users can access both cloud and on-premises apps and resources.

Azure AD-joined devices enable your users to access the following benefits:

- **SSO** Enables users simplified access to Azure-managed SaaS apps, services, and work resources.
- **Enterprise-compliant roaming** User settings can be roamed across joined devices using their Azure AD-joined devices (without the need to sign in using a Microsoft account).
- **Windows Hello** Devices can be secured using the enterprise features of Windows Hello.
- **Restriction of access** Devices can only access apps that meet the organizational compliance policy.
- **Seamless access to on-premises resources** Hybrid Azure AD-joined devices can access on-premises resources when connected to the domain network.

Organizations that already have Microsoft 365 or other SaaS apps integrated with Azure AD have the necessary components in place to have devices managed in Azure AD instead of being managed in Active Directory.

Enable device management

Device management requires configuration to ensure that when your users attempt device registration (register or join), the process doesn't fail. By default, the setting is enabled, allowing all Windows 11 devices with valid credentials to be managed by your Azure AD.

Typically, you'll use Microsoft Entra to configure the required settings. Use the following procedure to verify and, where necessary, update the settings:

1. Open the Microsoft Entra admin center.
2. Under **Azure Active Directory** in the navigation pane, select **Devices**, and then click **Overview**.
3. On the **Devices | Overview** page, click **Device settings**.
4. As shown in Figure 2-10, enable the **Users may join devices to Azure AD** setting. You can choose **All** to allow all users to perform this task, or you can choose **Selected** and choose which users can perform this task.
5. If necessary, also enable **Users may register their devices with Azure AD**.
6. Enable the **Require Multi-Factor Authentication to register or join devices with Azure AD** setting for additional security. However, you must ensure that users' accounts are configured with the necessary settings for MFA.
7. Finally, click the **Manage Additional local administrators on all Azure AD joined devices** link to add specified users as local administrators on joined devices. Any users you add are assigned to the Azure AD Joined Device Local Administrator role. This

setting ensures that a cloud user is always added as a local admin on all your organization's devices.

8. You can also enable the **Azure AD Local Administrator Password Solution (LAPS)** setting for any new devices.

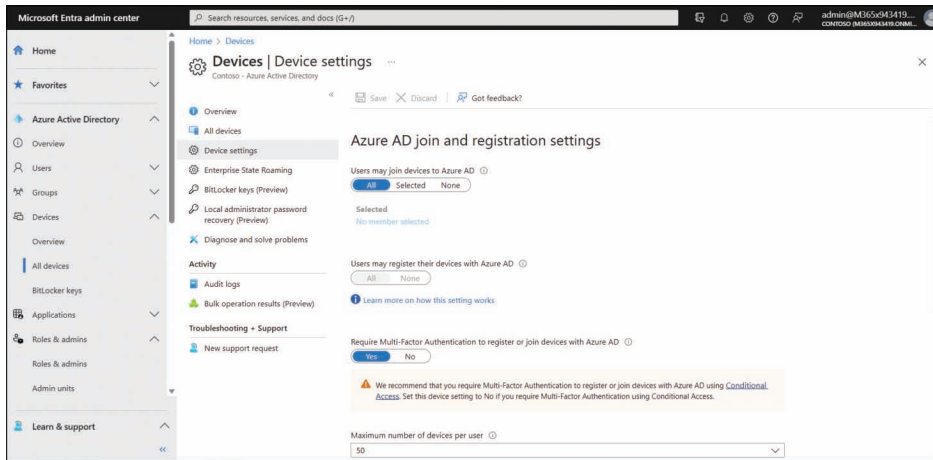

FIGURE 2-10 Configuring the settings for Azure AD registration or join

On the **Device settings** page, you can fine-tune the process of registering and joining devices by configuring the device settings, as shown in Table 2-1.

TABLE 2-1 Azure AD device configuration settings

Device setting	Description
Users May Join Devices To Azure AD	Allows you to select users that can join Windows 11 devices to Azure AD. The default is All.
Users May Register Their Devices With Azure AD	Allows devices to be registered with Azure AD by users. Options include: <ul style="list-style-type: none"> ■ None: Prevents devices from being registered with Azure AD. ■ All: Automatically configured if Enrollment with Microsoft Intune or Mobile Device Management (MDM) for Office 365 is configured as they require Device Registration.
Require Multi-Factor Authentication To Register Or Join Devices With Azure AD	Determines whether users are required to use multifactor authentication factor to join their devices to Azure AD. This setting only applies to Azure AD Join on Windows 11 and BYOD registration for Windows 11, iOS, and Android. This setting does not apply to hybrid Azure AD-joined devices, Azure AD-joined VMs in Azure, and Azure AD-joined devices using Windows Autopilot self-deployment mode. The default setting is No .
Maximum Number Of Devices Per User	Restricts the number of devices per user. Once this quota is reached, they cannot add devices until one or more existing devices are removed. The device quota is across both Azure AD-joined and Azure AD-registered devices. By default, all users can have a maximum of 50 devices in Azure AD.

Device setting	Description
Manage Additional Local Administrators On All Azure AD Joined Devices	Enables you to assign the users that are granted local administrator rights on a device and added to the Device Administrators role in Azure AD. By default, global administrators in Azure AD and device owners are granted local administrator rights. Requires an Azure AD Premium license.
Enable Azure AD Local Administrator Password Solution (LAPS)	Helps you securely manage the passwords of local accounts on joined devices. Defaults to No . This is discussed in more detail later in this chapter.
Restrict Users From Recovering The BitLocker Key(s) For Their Owned Devices	Determines if users can recover their BitLocker key(s). If enabled, the setting restricts non-admins from being able to access the BitLocker key(s) for their own devices. Selecting No enables users to recover their BitLocker key(s). Defaults to No .

Connect devices to Azure AD

Once the prerequisites have been configured to allow device registration service to take place, you can connect devices to Azure AD.

There are three ways to connect a Windows 11 device to Azure AD as follows:

- Join a new Windows 11 device to Azure AD
- Join an existing Windows 11 device to Azure AD
- Register devices to Azure AD

In this section, you'll learn the steps required to connect Windows 11 to Azure AD.

JOIN A NEW WINDOWS 11 DEVICE TO AZURE AD

In this method, you take a new Windows 11 device and join the device to Azure AD during the first-run experience.

NOTE OUT-OF-BOX-EXPERIENCE

The "first-run experience" is more usually known as the "out-of-box experience" (OOBE). OOBE runs when you start a computer for the first time, and a series of questions is displayed before you are presented with the Windows desktop.

The device could have been previously prepared using an enterprise deployment method, or it could have been distributed by the original equipment manufacturer (OEM) directly to your employees.

If the device is running either Windows 11 Professional or Windows 11 Enterprise, OOBE presents the setup process for company-owned devices.

To join a new Windows 11 device to Azure AD during OOBE, use the following steps:

1. Start the new device and allow the setup process to begin.
2. When prompted, on the **Is this the right country or region?** page, select your country or region, and click **Yes**.

3. On the **Is this the right keyboard layout or input method?** page, select the appropriate keyboard layout, and click **Yes**.
4. When prompted, if you want to add an additional keyboard layout, follow the steps to do so. Otherwise, click **Skip**.
5. Your computer checks for updates.
6. If prompted, review and **Accept** the License Agreement.
7. On the **Let's set things up for your work or school** page, as shown in Figure 2-11, in the **Sign in** box, enter your organizational user account and click **Next**.

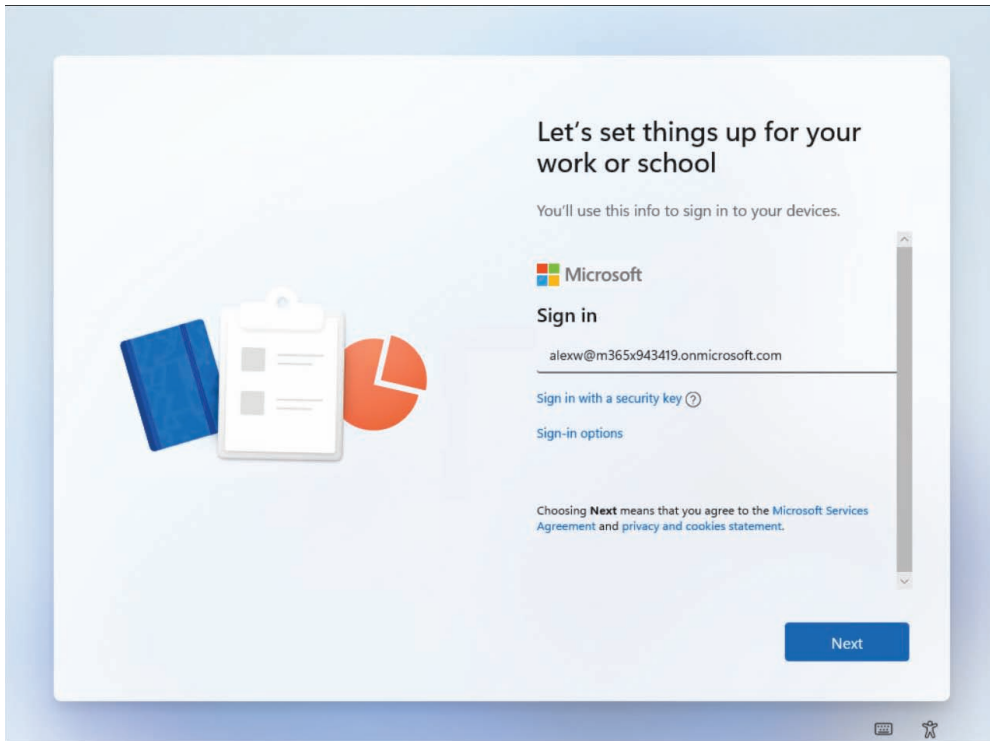

FIGURE 2-11 Joining a device to Azure AD during OOBET

8. When prompted, enter your password and click **Sign in**.
9. If your account requires it, you are prompted to identify yourself with MFA. This is configured at the organizational level but requires your user account to be configured.
10. The **Enrollment Status Page**, if configured, displays, as shown in Figure 2-12, guiding users during the device enrollment process.

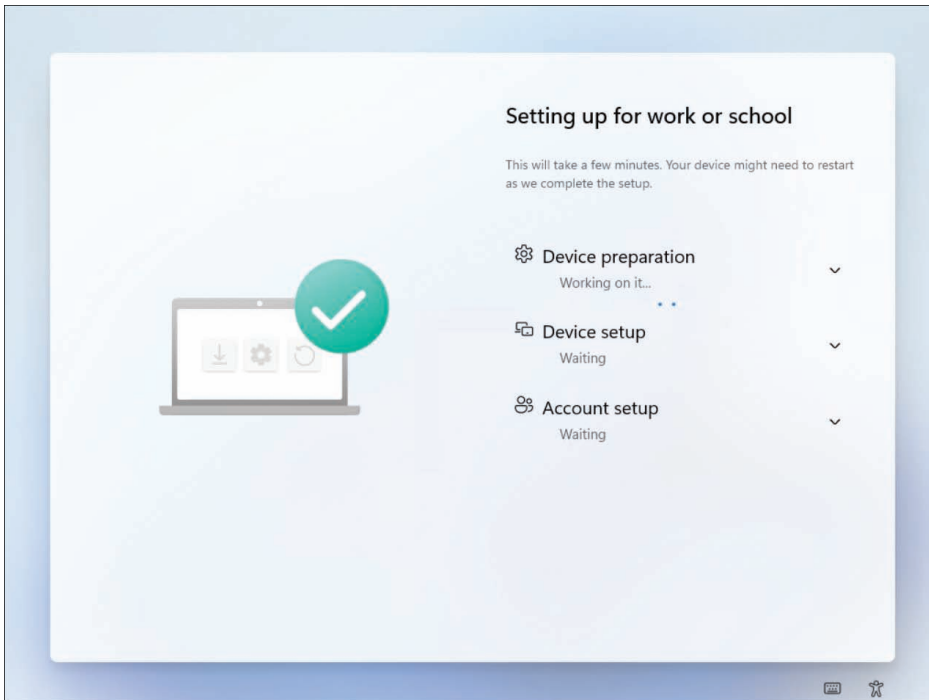

FIGURE 2-12 The device Enrollment Status Page displays

11. On the **Choose privacy settings for your device** page, click **Next** and then click **Accept**.
12. Your device checks for updates and might now return to **Device preparation**. You can, if prompted, click **Continue anyway** to allow this process to complete in the background.
13. If your organization requires it, you are now prompted to complete the Windows Hello setup. At the **Use Windows Hello with your account** page, click **OK**.
14. On the **Set up a PIN** page, in the **New PIN** and **Confirm PIN** boxes, enter a PIN that conforms to your organizational requirements and then click **OK**.
15. Click **OK**, and then you should be automatically signed in to the device, joined to your organization or school Azure AD tenant, and presented with the desktop.

JOIN AN EXISTING WINDOWS 11 DEVICE TO AZURE AD

In this method, we will join an existing Windows 11 device to Azure AD. You can join a Windows 11 device to Azure AD at any time. Use the following procedure to join the device:

1. Open the **Settings App** and then select **Accounts**.
2. In **Accounts**, select the **Access work or school** tab.
3. Select **Connect**.
4. On the **Set up a work or education account** page, under **Alternative actions**, select **Join this device to Azure Active Directory**, as shown in Figure 2-13.

 - baselines, implementing with Intune, 233–234
 - creating profiles, 234
 - updating profiles, 235
 - endpoint protection, 214
 - applying required security settings, 231–233
 - enterprise-level disk encryption, 215–218
 - Microsoft Defender Antivirus, 229–230
 - Microsoft Defender Application Control, 227–229
 - Microsoft Defender Application Guard, 225–227
 - Microsoft Defender Credential Guard, 218–220
 - Microsoft Defender Exploit Guard, 220–225
 - Microsoft Defender Firewall, 230–231
 - Microsoft Defender for Exploit, 236–239
 - enterprise-level disk encryption, 215
 - BitLocker, 215–218
 - TPM, 215
 - exploit protection, Microsoft Defender Exploit Guard, 220–223
 - firewalls, 230–231
 - Microsoft Defender Antivirus, 229–230

- Microsoft Defender Application Control, 227
 - default policies, 228
 - enabling, 228–229
- Microsoft Defender Application Guard, 225–227
- Microsoft Defender Credential Guard, 218–220
- Microsoft Defender Exploit Guard, 220
 - Attack Surface Reduction rules, 223–224
 - Controlled Folder Access, 224
 - exploit protection, 220–223
 - features, 220
 - implementing, 224–225
 - Network Protection, 224
 - sign apps, 227–228
- Microsoft Defender Firewall, 230–231
- Microsoft Defender for Exploit, 236–239
 - viruses, 229–230
- selecting deployment tools, Windows client, 2
- service, Windows as a, 202–204
- servicing channels, device updates, 203–204
- sideloading apps, 285–288
- sign apps, Microsoft Defender Application Control, 227–228
- special identity groups, 115–118
- study plans, MD-102 Endpoint Administrator exam, 306
- subscription-based activation, Windows 11, 21–28
- System Center Configuration Manager, device hardware information, 33

T

- task sequences, Windows client MDT deployments, 47–48
- technical content updates, MD-102 Endpoint Administrator exam, 306
- terms and conditions, device enrollment settings, 146
- thick images, Windows client MDT deployments, 43
- thin images, Windows client MDT deployments, 43
- TPM (Trusted Platform Modules), 215
- troubleshooting
 - compliance policies, 130–132
 - device configuration profiles, 177–183
 - device updates, 212–214
 - Intune troubleshooting portal, 181–183
 - provisioning packages, 9–10
 - Remote Desktop connections, 70
 - Windows AutoPilot, 39–42
 - Windows client MDT deployments, 50–51
- tunneling, Microsoft Tunnel for Intune, 187–192

U

- updating
 - devices, 201
 - Android devices, 211
 - creating policies, 209–210
 - deferrals, 202–203
 - deployment rings, 204–206
 - iOS device policies, 209
 - macOS device policies, 210
 - monitoring, 212

 - servicing channels, 203–204
 - troubleshooting, 212–214
 - viewing update histories, 213–214
 - Windows as a service, 202–204
 - Windows Delivery Optimization, 206–209
 - MD-102 Endpoint Administrator exam, 306
 - objective updates, 306
 - technical content updates, 306
 - policies, 209–210
 - security baseline profiles, 235
 - upgrade/downgrade paths, Windows client deployments, 17–21
 - upgrading Windows 11, 19–21
 - user authentication, Azure AD, 86–93
 - device management, 97–107
 - RBAC, 94–97
 - role assignments in groups, 96
 - user-driven Windows client deployments, 12
 - user role assignments, Remote Help, 61
 - user state Windows client migrations, 51–55
 - USMT (User State Migration Tool)
 - accessible data types, 53–54
 - components, 54–55
 - Windows client deployments, 52–55

V

- viewing update histories, 213–214
- viruses, Microsoft Defender Antivirus, 229–230
- VPN, Microsoft Tunnel for Intune, 187–192

W

- Win32 app, deploying Remote Help as, 57–60
- Windows 11
 - accounts, 86–87
 - block switching, 21
 - S mode, 20–21
 - subscription-based activation, 21–28
 - upgrading, 19
- Windows ADK, downloading, 4
- Windows Admin Center
 - authentication, 72
 - configuring, 70
 - installing, 71
 - using, 72–74
- Windows as a service, updating devices, 202–204
- Windows AutoPilot
 - deployment profile settings, 28–31
 - overview, 12–13
 - troubleshooting, 39–42
 - Windows client deployments, 12–13, 37–42
- Windows client deployments
 - Configuration Manager, 15–16
 - deployment profiles
 - company branding, 31
 - creating, 29–31
 - extracting device hardware information, 31–33
 - importing device hardware information to cloud service, 33–34
 - downgrade/upgrade paths, 17–21
- dynamic provisioning, 3–4
 - methods, 3
 - provisioning packages, 4–10
- ESP, 34–37, 38–39
- imaging strategies, 11–16
- MDT, 13–15, 42
 - adding images to MDT, 45–46
 - applications, 46
 - boot images, 43
 - creating reference images, 44–45
 - custom images, 43
 - default images, 42–43
 - deploying images, 49–50
 - drivers, 47

Windows client deployments, *continued*

- monitoring, 50–51
- operating system images, 43
- task sequences, 47–48
- thick images, 43
- thin images, 43
- troubleshooting, 50–51
- methods (overview), 2
- migrating data, 10
- PowerShell remoting, 74
 - configuring, 74–76
 - using, 76–77
- preparing for (overview), 1
- provisioning strategies, 11–16
- rebuilding new computers, 10–11
- Remote Desktop, 64–65
 - creating connections, 66–68
 - customizing from command line, 68–70
 - enabling, 65–66
 - troubleshooting connections, 70
- selecting
 - deployment tools, 2
- Windows edition based on requirements, 17
- subscription-based activation, 21–28
- user-driven deployments, 12
- user state migrations, 51–55
- USMT, 53–55

- Windows Admin Center, 70
 - authentication, 72
 - installing, 71
 - using, 72–74
- Windows AutoPilot, 12–13, 28–31
- ZTI, 14
- Windows Delivery Optimization, device updates, 206–209
- Windows device profiles, 166–167
- Windows editions, selecting for Windows client deployments, 17
- Windows Health Attestation, 197
- Windows Hello, 88–90
 - biometrics, 90
 - PIN, 90–92
- Windows Hello for Business, 88–90
 - configuring, 93
 - Group Policy, 92–93
- Windows Kiosk mode, 183–186
- WinRM (Windows Remote Management), 75
- wiping devices, 162–163

X - Y - Z
